(54) Title: FARNESYL PROTEIN TRANSFERASE INHIBITOR COMBINATIONS WITH ANTIESTROGEN AGENTS

(57) Abstract: The present invention is concerned with combinations of a farnesyl transferase inhibitor and an antiestrogen agent for inhibiting the growth of tumor cells, useful in the treatment of cancer.

FARNESYL PROTEIN TRANSFERASE INHIBITOR COMBINATIONS WITH ANTIESTROGEN AGENTS

The present invention is concerned with combinations of a farnesyl transferase inhibitor and an antiestrogen agent for inhibiting the growth of tumor cells, and useful in the treatment of cancer.

Oncogenes frequently encode protein components of signal transduction pathways which lead to stimulation of cell growth and mitogenesis. Oncogene expression in cultured cells leads to cellular transformation, characterized by the ability of cells to grow in soft agar and the growth of cells as dense foci lacking the contact inhibition exhibited by non-transformed cells. Mutation and/or overexpression of certain oncogenes is frequently associated with human cancer. A particular group of oncogenes is known as *ras* which have been identified in mammals, birds, insects, mollusks, plants, fungi and yeasts. The family of mammalian *ras* oncogenes consists of three major members ("isoforms") : H-*ras*, K-*ras* and N-*ras* oncogenes. These *ras* oncogenes code for highly related proteins generically known as $p21^{ras}$. Once attached to plasma membranes, the mutant or oncogenic forms of $p21^{ras}$ will provide a signal for the transformation and uncontrolled growth of malignant tumor cells. To acquire this transforming potential, the precursor of the $p21^{ras}$ oncoprotein must undergo an enzymatically catalyzed farnesylation of the cysteine residue located in a carboxyl-terminal tetrapeptide. Therefore, inhibitors of the enzyme that catalyzes this modification, farnesyl protein transferase, will prevent the membrane attachment of $p21^{ras}$ and block the aberrant growth of *ras*-transformed tumors. Hence, it is generally accepted in the art that farnesyl transferase inhibitors can be very useful as anticancer agents for tumors in which *ras* contributes to transformation.

Since mutated, oncogenic forms of *ras* are frequently found in many human cancers, most notably in more than 50 % of colon and pancreatic carcinomas (Kohl et al., *Science*, vol 260, 1834 - 1837, 1993), it has been suggested that farnesyl tranferase inhibitors can be very useful against these types of cancer. Following further investigations, it has been found that a farnesyl transferase inhibitor is capable of demonstrating antiproliferative effects *in vitro* and antitumor effects *in vivo* in a variety of human tumor cell lines with and without ras gene mutations.

Many breast cancers have estrogen receptors and growth of these tumors can be stimulated by estrogen. Antiestrogen agents have therefore been proposed and used for the treatment of cancers especially breast cancer. One of the most widely used of such agents is tamoxifen which is a competitive inhibitor of estradiol binding to the estrogen receptor (ER). When bound to the ER, tamoxifen induces a change in the three-dimensional shape of the receptor, inhibiting its binding to the estrogen responsive element (ERE) on DNA. Under normal physiological conditions, estrogen stimulation increases tumor cell production of transforming growth cell b (TGF-b), an autocrine inhibitor of tumor cell growth. By blocking these pathways, the net effect of tamoxifen treatment is to decrease the autocrine stimulation of breast cancer growth. In addition, tamoxifen decreases the local production of insulin-like growth factor (IGF-1) by surrounding tissues: IGF-1 is a paracrine growth factor for the breast cancer cell (Jordan and Murphy, Endocr. Rev., 1990, 11; 578-610). Tamoxifen is the endocrine treatment of choice for post-menopausal women with metastatic breast cancer or at a high risk of recurrences from the disease. Tamoxifen is also used in pre-menopausal women with ER-positive tumors. There are various potential side-effects of long-term tamoxifen treatment for example the possibility of endometrial cancer and the occurrence of thrombo-embolic events. Thus, although tamoxifen has been widely used as a chemotherapeutic agent in humans, it is not therapeutically effective in all patients or against all types of tumors. Other estrogen receptor antagonists or selective estrogen receptor modulators include toremifene, droloxifene, faslodex and raloxifene.

In postmenopausal women, the principal source of circulating estrogen is from conversion of adrenal and ovarian androgens (androstenedione and testosterone) to estrogens (estrone and estradiol) by the aromatase enzyme in peripheral tissues. Estrogen deprivation through aromatase inhibition or inactivation is an effective and selective treatment for some postmenopausal patients with hormone-dependent breast cancer. Examples of aromatase inhibitors or inactivators include exemestane, anastrozole, letrazole and vorozole.

The term "antiestrogen agent" is used herein to include not only estrogen receptor antagonists and selective estrogen receptor modulators but also aromatase inhibitors as discussed above.

WO-01/45740 describes compositions and methods for treating and/or preventing breast cancer including compositions comprising at least one selective estrogen receptor modulator for example tamoxifen and at least one farnesyl transferase inhibitor for example FTI-277.

There is a need to increase the inhibitory efficacy of antiestrogen agents against tumor growth and also to provide a means for the use of lower dosages of such agents to reduce the potential of adverse toxic side effects to the patient.

It is an object of the invention to provide a therapeutic combination of an antiestrogen agent and a farnesyl transferase inhibitor of the type described above which has an advantageous inhibitory effect against tumor cell growth, in comparison with the respective effects shown by the individual components of the combination.

According to the invention therefore we provide a combination of an antiestrogen agent and a farnesyl transferase inhibitor of formula (I), (II), (III), (IV), (V), (VI), (VII), (VIII) or (IX) above, in particular a compound of formula (I), (II) or (III):

A particularly preferred antiestrogen agent for use in accordance with the invention is tamoxifen. Tamoxifen is commercially available for example from AstraZeneca plc under the trade name Nolvadex and may be prepared for example as described in GB Patent Specifications 1064629 and 1354939 or by processes analogous thereto. Other antiestrogen agents include faslodex commercially available for example from AstraZeneca plc under the trade name Fulvestrant, raloxifene commercially available

for example from Eli Lilly under the trade name Evista, toremifene commercially available for example from Schering Corporation under the trade name Fareston, and the tamoxifen analog droloxifene. Aromatase inhibitors include letrazole, anastrozole commercially available for example from AstraZeneca plc under the trade name Arimidex, exemestane commercially available for example from Pharmacia & Upjohn under the trade name under the trade name Aromasin, and vorozole.

The present invention also relates to combinations according to the invention for use in medical therapy for example for inhibiting the growth of tumor cells.

The present invention also relates to the use of combinations according to the invention for the preparation of a pharmaceutical composition for inhibiting the growth of tumor cells.

The present invention also relates to a method of inhibiting the growth of tumor cells in a human subject which comprises administering to the subject an effective amount of a combination according to the invention.

This invention further provides a method for inhibiting the abnormal growth of cells, including transformed cells, by administering an effective amount of a combination according to the invention. Abnormal growth of cells refers to cell growth independent of normal regulatory mechanisms (e.g. loss of contact inhibition). This includes the abnormal growth of : (1) tumor cells (tumors) expressing an activated *ras* oncogene; (2) tumor cells in which the *ras* protein is activated as a result of oncogenic mutation of another gene; (3) benign and malignant cells of other proliferative diseases in which aberrant *ras* activation occurs. Furthermore, it has been suggested in literature that *ras* oncogenes not only contribute to the growth of of tumors *in vivo* by a direct effect on tumor cell growth but also indirectly, *i.e.* by facilitating tumor-induced angiogenesis (Rak. J. et al, *Cancer Research*, 55, 4575-4580, 1995). Hence, pharmacologically targetting mutant *ras* oncogenes could conceivably suppress solid tumor growth *in vivo*, in part, by inhibiting tumor-induced angiogenesis.

This invention also provides a method for inhibiting tumor growth by administering an effective amount of a combination according to the present invention, to a subject, e.g. a mammal (and more particularly a human) in need of such treatment. In particular, this invention provides a method for inhibiting the growth of tumors expressing an activated *ras* oncogene by the administration of an effective amount of combination

according to the present invention. The present invention is particularly applicable to the treatment of breast cancer including the advanced disease. Examples of other tumors which may be inhibited include, but are not limited to, lung cancer (e.g. adenocarcinoma and including non-small cell lung cancer), pancreatic cancers (e.g. pancreatic carcinoma such as, for example exocrine pancreatic carcinoma), colon cancers (e.g. colorectal carcinomas, such as, for example, colon adenocarcinoma and colon adenoma), hematopoietic tumors of lymphoid lineage (e.g. acute lymphocytic leukemia, B-cell lymphoma, Burkitt's lymphoma), myeloid leukemias (for example, acute myelogenous leukemia (AML)), thyroid follicular cancer, myelodysplastic syndrome (MDS), tumors of mesenchymal origin (e.g. fibrosarcomas and rhabdomyosarcomas), melanomas, teratocarcinomas, neuroblastomas, gliomas, benign tumor of the skin (e.g. keratoacanthomas), kidney carninoma, ovary carcinoma, bladder carcinoma and epidermal carcinoma.

This invention also provides a method for inhibiting proliferative diseases, both benign and malignant, wherein *ras* proteins are aberrantly activated as a result of oncogenic mutation in genes, i.e. the *ras* gene itself is not activated by mutation to an oncogenic mutation to an oncogenic form, with said inhibition being accomplished by the administration of an effective amount of a combination according to the invention, to a subject in need of such a treatment. For example, the benign proliferative disorder neurofibromatosis, or tumors in which *ras* is activated due to mutation or overexpression of tyrosine kinase oncogenes may be inhibited by the combinations according to the invention.

The antiestrogen agent and the farnesyl transferase inhibitor may be administered simultaneously (e.g. in separate or unitary compositions) or sequentially in either order. In the latter case, the two compounds will be administered within a period and in an amount and manner that is sufficient to ensure that an advantageous or synergistic effect is achieved. It will be appreciated that the preferred method and order of administration and the respective dosage amounts and regimes for each component of the combination will depend on the particular antiestrogen agent and the farnesyl transferase inhibitor being administered, the route of administration of the combination, the particular tumor being treated and the particular host being treated. The optimum method and order of administration and the dosage amounts and regime can be readily determined by those skilled in the art using conventional methods and in view of the information set out herein.

The farnesyl transferase inhibitor is advantageously administered in an effective amount of from 0.0001 mg/kg to 100 mg/kg body weight, and in particular from 0.001 mg/kg to 10 mg/kg body weight. More particularly, for an adult patient, the dosage is conveniently in the range of 50 to 500mg bid, advantageously 100 to 400 mg bid and particularly 300mg bid.

The antiestrogen agent is advantageously administered in a dosage of about 1 to 100mg daily depending on the particular agent and the condition being treated. Tamoxifen is advantageously administered orally in a dosage of 5 to 50 mg, preferably 10 to 20 mg twice a day, continuing the therapy for sufficient time to achieve and maintain a therapeutic effect. Toremifene is advantageously administered orally in a dosage of about 60mg once a day, continuing the therapy for sufficient time to achieve and maintain a therapeutic effect. Anastrozole is advantageously administered orally in a dosage of about 1mg once a day. Droloxifene is advantageously administered orally in a dosage of about 20-100mg once a day. Raloxifene is advantageously administered orally in a dosage of about 60mg once a day. Exemestane is advantageously administered orally in a dosage of about 25mg once a day.

It is especially preferred to administer the farnesyl tranferase inhibitor at a dosage of 100 or 200mg bid for 7, 14, 21 or 28 days with a dosage of the antiestrogen agent in the ranges indicated above.

In view of their useful pharmacological properties, the components of the combinations according to the invention, i.e. the antiestrogen agent and the farnesyl transferase inhibitor may be formulated into various pharmaceutical forms for administration purposes. The components may be formulated separately in individual pharmaceutical compositions or in a unitary pharmaceutical composition containing both components. Farnesyl protein transferase inhibitors can be prepared and formulated into pharmaceutical compositions by methods known in the art and in particular according to the methods described in the published patent specifications mentioned herein and incorporated by reference; for the compounds of formulae (I), (II) and (III) suitable examples can be found in WO-97/21701. Compounds of formulae (IV), (V), and (VI) can be prepared and formulated using methods described in WO 97/16443, compounds of formulae (VII) and (VIII) according to methods described in WO 98/40383 and WO 98/49157 and compounds of formula (IX) according to methods described in WO 00/39082 respectively.

The present invention therefore also relates to a pharmaceutical composition comprising an antiestrogen agent and a farnesyl tranferase inhibitor of formula (I) together with one or more pharmaceutical carriers. To prepare pharmaceutical compositions for use in accordance with the invention, an effective amount of a particular compound, in base or acid addition salt form, as the active ingredient is combined in intimate admixture with a pharmaceutically acceptable carrier, which carrier may take a wide variety of forms depending on the form of preparation desired for administration. These pharmaceutical compositions are desirably in unitary dosage form suitable, preferably, for administration orally, rectally, percutaneously, or by parenteral injection. For example, in preparing the compositions in oral dosage form, any of the usual pharmaceutical media may be employed, such as, for example, water, glycols, oils, alcohols and the like in the case of oral liquid preparations such as suspensions, syrups, elixirs and solutions; or solid carriers such as starches, sugars, kaolin, lubricants, binders, disintegrating agents and the like in the case of powders, pills, capsules and tablets. Because of their ease in administration, tablets and capsules represent the most advantageous oral dosage unit form, in which case solid pharmaceutical carriers are obviously employed. For parenteral compositions, the carrier will usually comprise sterile water, at least in large part, though other ingredients, to aid solubility for example, may be included. Injectable solutions, for example, may be prepared in which the carrier comprises saline solution, glucose solution or a mixture of saline and glucose solution. Injectable suspensions may also be prepared in which case appropriate liquid carriers, suspending agents and the like may be employed. In the compositions suitable for percutaneous administration, the carrier optionally comprises a penetration enhancing agent and/or a suitable wetting agent, optionally combined with suitable additives of any nature in minor proportions, which additives do not cause a significant deleterious effect to the skin. Said additives may facilitate the administration to the skin and/or may be helpful for preparing the desired compositions. These compositions may be administered in various ways, e.g., as a transdermal patch, as a spot-on, as an ointment.

It is especially advantageous to formulate the aforementioned pharmaceutical compositions in dosage unit form for ease of administration and uniformity of dosage. Dosage unit form as used in the specification and claims herein refers to physically discrete units suitable as unitary dosages, each unit containing a predetermined quantity of active ingredient calculated to produce the desired therapeutic effect in association with the required pharmaceutical carrier. Examples of such dosage unit forms are tablets (including scored or coated tablets), capsules, pills, powder packets,

wafers, injectable solutions or suspensions, teaspoonfuls, tablespoonfuls and the like, and segregated multiples thereof.

It may be appropriate to administer the required dose of each component of the combination as two, three, four or more sub-doses at appropriate intervals throughout the course of treatment. The sub-doses may be formulated as unit dosage forms, for example, in each case containing independently 0.01 to 500 mg, for example 0.1 to 200 mg and in particular 1 to 100mg of each active ingredient per unit dosage form.

Anti-tumor Activity of a Combination of a Farnesyl Transferase Inhibitor and an Anti-estrogen Agent

A combination of a farnesyl transferase inhibitor, namely the compound identified as Compound 75 above (R115777), and an anti-estrogen agent, namely tamoxifen (TMX), was tested for anti-tumor activity in comparison with the activity of the individual components of the combination, as described below.

Mice/Husbandry

Female Nude-Homo NCRNU non-ovarectimized mice 8 weeks of age were fed ad libitum water and an irradiated standard rodent diet. Mice were housed in stable microisolators on a 12 hour light cycle at 21-22° C and 40-60 % humidity.

Tumors

Mice were inoculated subcutaneously with 1×10^7 MCF7 human breast carcinoma cells in the flank. Tumors were monitored initially twice a week and then daily as neoplasms reached the desired size, approximately 100mg. When the carcinomas reached a size between 62-144 mg in calculated tumor weight, the animals were pair matched into the various treatment groups (group mean tumor weights ranged from 83-85mg).

Estimated tumor weight was calculated using the formula:

$$\text{Tumor Weight (mg)} = \frac{w^2 \times l}{2}$$

w= width and l=length in mm of a MCF7 tumor

Estrogen pellets (0.36 mg: α-estradiol, 60 day release) were implanted s.c. in the dorsal region of each mouse two days prior to MCF7 cell inoculation. Fresh estrogen pellets were implanted 64 days after the original implant. On Day 1 the estrogen pellets were

removed from the two groups administered Tamoxifen (Groups 3 and 5). The pellets were left in place in Groups 1, 2 and 4, and new estrogen pellets were implanted in mice in Groups 1,2 and 4 on Day 62 of the experiment. The old pellets were not removed from these groups at the time of replacement. The MCF7 breast tumor xenograft requires exogenous estrogen to be supplied to host mice to support the progressive growth of this carcinoma.

Drugs

The vehicle was 20% beta-cyclodextrin in 0.1N HCl. Beta-cyclodextrin was added slowly to a constantly stirred approximate volume of 0.1 N HCl to yield a 40% beta-cyclodextrin solution. The mixture was covered with foil and stirred until completely dissolved (several hours). The solution was then brought to final volume and filtered (0.2μm).

R115777 was dissolved in batches sufficient for seven days dosing at a time. R115777 was pulse sonicated for 10 minutes at 4°C, filtered (0.2µm) and transferred to sterile 15 or 50ml vials. This solution was further diluted using 20% beta-dextrin in 0.1 N HCl for lower concentration dose groups. Vials were wrapped in foil and stored at 4°C. The dosing volume (0.2ml/20g mouse) was weight adjusted.

Tamoxifen was reconstituted in corn oil at 10mg/ml. Dosing was not body weight adjusted; each mouse received 100 μL of the solution (1mg/mouse).

Treatment Plan

MCF-bearing nude mice were pair-matched on Day1 into five groups of twelve animals each. Tamoxifen was given s.c. at a dose of 1mg/mouse qd to end. R115777 was administered orally at 100mg/kg qd to end. The combination therapy group used the same regimens as were employed in the Tamoxifen and R115777 monotherapy groups. A growth control (no treatment group) and a vehicle control group were included in the study. Estrogen pellets were removed from the Tamoxifen monotherapy and the combination therapy groups on Day1, to avoid antagonizing the Tamoxifen antiestrogen effect

End point

The tumor growth inhibition (TGI) endpoint was used in this study to assess the efficacy of the various treatments. The tumor burden endpoint was set at 1.0g as measured by calliper. TGI values were determined on the last day of the study (Day 5), when all mice were under test, except those that had expired from treatment-related or

procedural causes. The mice were euthanized at termination, their MCF7 tumors were excised and weighed, and the TGI values were calculated from the final group mean carcinoma actual weights (excluding those that underwent tumor shrinkage; CRs or PRs).

At excision, tumors smaller than their size on Day 1 were called PRs (partial regressions), and a mouse with no visible carcinoma was termed a CR (complete regression).

Animals recorded as CRs or PRs were not included in the TGI calculations. The following formula was used to calculate the TGI values:

$$\%TGI = \left[1 - \left(\frac{\text{Mean Net Tumor Weight}_{\text{Treated}}}{\text{Mean Net Tumor Weight}_{\text{Control}}}\right)\right] \times 100\%$$

Sample Collection

At endpoint, tumors were removed and weighed. At their endpoint, after Day 27, each tumor was cut in half with a scalpel and half was placed in fifteen to twenty volumes of 10% neutral buffered formalin. The other half was snap-frozen in liquid nitrogen and stored at -80°C. At their endpoint, after Day 30, blood was collected from the remaining mice of Groups 3, 4 and 5 by cardiac puncture under CO_2 anesthesia. Serum was recovered, and stored at –80°C until the end of the study.
